Part A

1. Go back to your `ListOfInts` class files from Lab 5A and add an **overloaded stream insertion operator <<** which can be used for output of the List. If the List is empty this should output an "Empty List" message.

2. Now add a **copy constructor** and an **overloaded assignment operator** for your list classes (Node and List).

Part B

3. Now make a `Book` Class. A Book has only two attributes, isbn (integer) and title (string), and corresponding accessor and mutator methods.

4. Make a `NodeofBook` class. A Node of Book only has two private member variables: `Book theBook`, and `NodeofBook *next`, and a constructor that sets values for the Book's isbn and title, and the pointer to `NullPtr` .

5. Make a Linked List of Books class, which should have all the same members functions as the `ListOfInts` class.

6. Implement a main function (in a separate source.cpp file) to test your ListofBooks class functionality.
